

<https://video.marvice.tech>

How it works, step by step

HyperFrames Studio on our own Coolify server: write HTML,
preview it, render it to MP4.

THE BIG PICTURE

One visit passes through five stops

Traefik, Caddy and Studio all run on one Hostinger VPS, managed by **Coolify**. Only the first three stops are public; Studio sits behind the login.

STEP 1 • DNS

The name points to our server

When you type **video.marvice.tech**, your computer asks Hostinger's DNS where that name lives. One A record answers: our Coolify server, the same machine behind coolify, n8n and crm.

Hostinger · marvice.tech · DNS records

Type	Name	Points to
A	video	91.108.110.216
A	coolify	91.108.110.216
A	n8n	91.108.110.216

Highlighted row: the record added for this site (TTL 300 s)

The server's front door adds HTTPS

Certificate

Coolify's proxy, Traefik, gets a free Let's Encrypt certificate for video.marvice.tech and renews it automatically.

Redirect

Plain http:// visits are sent to https:// so the password never travels unencrypted.

Routing

It reads the name in the request and hands the visit to our login gate on port 8080.

STEP 3 • CADDY

A login gate guards the studio

HyperFrames Studio has no login of its own: anyone who reached it could read, change or delete files and start renders. So a small Caddy server stands in front and checks the username and password first.

401	No password → login prompt
401	Wrong password → refused
200	Right password → Studio opens

Username and password live in Coolify as BASIC_AUTH_USER and BASIC_AUTH_PASSWORD.

Videos are written as web pages

01 • Write

A video is HTML, CSS and animation, with media files beside it.

02 • Preview

Studio plays it in the browser and reloads on every save.

03 • Render

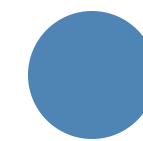

Chromium captures each frame; ffmpeg turns them into an MP4.

It runs in its own container with Node 22, Chromium and ffmpeg — HyperFrames version 0.8.140, open source from HeyGen.

STEP 5 • STORAGE

Your work is kept on the server

Projects live in a saved Docker volume, not inside the container. Redeploys, restarts and upgrades replace the container but leave the volume alone.

hyperframes-projects

/projects

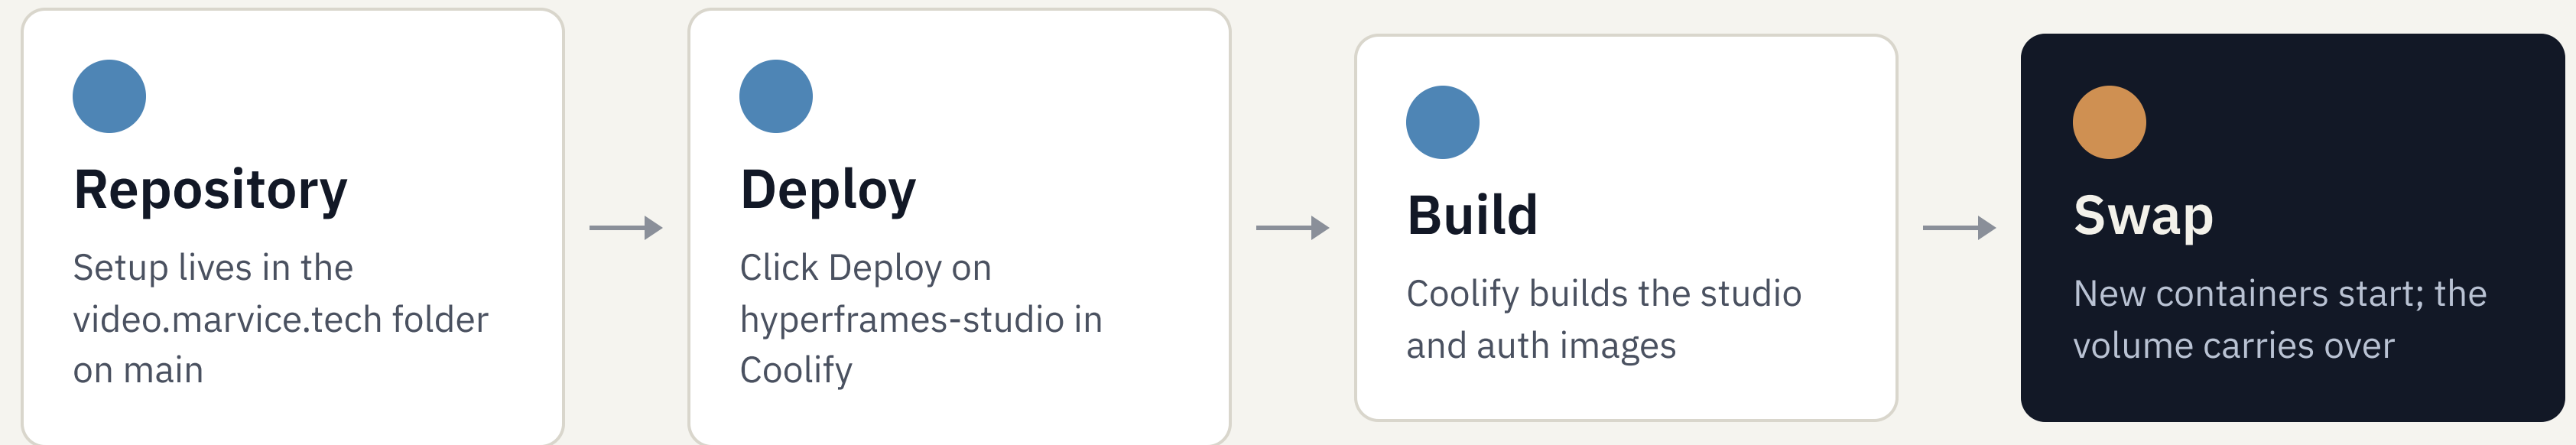

└ studio/ ← first project

└ ... more projects

On first start the container creates the studio project here automatically.

HOW CHANGES GO LIVE

From GitHub to the live site in four moves

Files: Dockerfile, entrypoint.sh, docker-compose.yml, and the Caddy gate (Dockerfile.auth, Caddyfile, auth-entrypoint.sh).

EVERYDAY TASKS

What to do when...

You want to...	Do this in Coolify (hyperframes-studio)
Change the password	Edit BASIC_AUTH_PASSWORD, then Redeploy
Upgrade HyperFrames	Set HYPERFRAMES_VERSION, then Redeploy
Fix a certificate warning	Restart the app so Traefik asks Let's Encrypt again
Check it's healthy	Open Logs; status should read Running
Change the setup files	Merge to main in GitHub, then Deploy

One address, one login, one saved workspace.

TO DO

Change the Studio password
from the one set at launch

TO DO

Rotate the Hostinger and Coolify
API tokens

TO TRY

Render a short MP4 to confirm
export works
